Abstract

Hepatocellular carcinoma (HCC) is common malignant tumor in Taiwan, and the therapeutic methods depend on the Barcelona clinic liver cancer (*BCLC*) stage, a set of criteria about treatment options including the images presentation of tumor, the liver function as Child-Pugh score, and the performance status(PS, or Eastern Cooperative Oncology Group , ECOG).

An advanced stage HCC with portal invasion was traditionally considered to receive palliative treatment including transarterial embolism/ chemoembolism (TAE or TACE), radiotherapy, systemic chemotherapy and target therapy with Sorafenib or supportive care with hospice. However, based on the malignancy presentation, some selected conditions might consider possible surgical resection for curative treatment.

Keywords: Hepatocellular carcinoma, BCLC stage, therapeutic method
