Abstract:

This 94-years-old man present to ER with chief complaint of coffee ground substance vomiting at home for days. He has been under regular medication with clopidogrel for years for his ischemic stroke. EGD disclosed only esophageal ulcer and gastric ulcer without active bleeder. However, he still persistently had tarry stool passage. Leukopenia, thrombocytopenia and bandemia developed. Fever workup showed negative finding in respiratory tract and urinary tract. Patient started to have poor appetite with distended abdomen with impaired consciousness. He did not have abdominal pain. Physical exam showed tympany and hypoactive bowel sound. CT of abdomen was performed to further exclude intraabdominal infection, which it revealed ileocecal intussusception. Under the impression of ileocecal intussusception with severe sepsis, patient was transferred to medical center for surgical evaluation.

We report a case of adult intussusception in ileocecal colon caused by lipoma. Further literature review was made focusing on the intussusception caused by lipoma in adult.
